Python Programming Fundamentals Cheat Sheet

Package/Method	Description	Syntax and Code Example
AND	Returns `True` if both statement1 and statement2 are `True`. Otherwise, returns `False`.	<pre>Example: marks = 90 attendance_percentage = 87 if marks >= 80 and attendance_percentage >= 85: print("qualify for honors") else: print("Not qualified for honors") # Output = qualify for honors</pre>
Class Definition	Defines a blueprint for creating objects and defining their attributes and behaviors.	<pre>Syntax: class ClassName: # Class attributes and methods Example: class Person: definit(self, name, age): self.name = name self.age = age</pre>
Define Function	A`function` is a reusable block of code that performs a specific task or set of tasks when called.	Syntax: def function_name(parameters): # Function body Example: def greet(name): print("Hello,", name)

about:blank 1/10

3/10/2025, 16:33		about:blank
		Syntax: variable1 == variable2 Example 1:
Equal(==)	Checks if two values are equal.	5 == 5
		returns True Example 2: age = 25 age == 30 returns False
For Loop	A`for` loop repeatedly executes a block of code for a specified number of iterations or over a sequence of elements (list, range, string, etc.).	<pre>Syntax: for variable in sequence: # Code to repeat Example 1: for num in range(1, 10): print(num) Example 2: fruits = ["apple", "banana", "orange", "grape", "kiwi"] for fruit in fruits: print(fruit)</pre>

about:blank 2/10

03/10/2025, 16:33	1	about:blank
Function Call	A function call is the act of executing the code within the function using the provided arguments.	Syntax: function_name(arguments) Example: greet("Alice")
Greater Than or Equal To(>=)	Checks if the value of variable 1 is greater than or equal to variable 2.	Syntax: variable1 >= variable2 Example 1: 5 >= 5 and 9 >= 5
		returns True Example 2: quantity = 105 minimum = 100 quantity >= minimum returns True
Greater Than(>)	Checks if the value of variable1 is greater than variable2.	Syntax: variable1 > variable2 Example 1: 9 > 6 returns True Example 2:

```
age = 20
                                                                                                          max\_age = 25
                                                                                                          age > max_age
                                                                                                  returns False
                                                                                                  Syntax:
                                                                                                          if condition: #code block for if statement
If Statement
                             Executes code block `if` the condition is `True`.
                                                                                                  Example:
                                                                                                         if temperature > 30:
    print("It's a hot day!")
                                                                                                  Syntax:
                                                                                                         if condition1:
# Code if condition1 is True
                                                                                                         elif condition2:
# Code if condition2 is True
                                                                                                         else:
                                                                                                          # Code if no condition is True
                             Executes the first code block if condition1 is `True`,
If-Elif-Else
                             otherwise checks condition2, and so on. If no condition
                                                                                                  Example:
                             is `True`, the else block is executed.
                                                                                                         score = 85  # Example score
if score >= 90:
    print("You got an A!")
elif score >= 80:
    print("You got a B.")
else:
                                                                                                         print("You need to work harder.")
# Output = You got a B.
If-Else Statement
                             Executes the first code block if the condition is `True`,
                                                                                                  Syntax:
                             otherwise the second block.
                                                                                                         if condition: # Code, if condition is True else: # Code, if condition is False
```

about:blank 4/10

```
Example:
                                                                                               if age >= 18:
    print("You're an adult.")
else:
                                                                                                    print("You're not an adult yet.")
                                                                                        Syntax:
                                                                                               variable1 <= variable2</pre>
                                                                                        Example 1:
                                                                                               5 <= 5 and 3 <= 5
                          Checks if the value of variable1 is less than or equal to variable2.
Less Than or Equal
To(<=)
                                                                                        returns True
                                                                                        Example 2:
                                                                                               size = 38
max_size = 40
size <= max_size</pre>
                                                                                        returns True
                          Checks if the value of variable1 is less than variable2.
Less Than(<)
                                                                                        Syntax:
                                                                                               variable1 < variable2</pre>
                                                                                        Example 1:
                                                                                              4 < 6
                                                                                        returns True
```

```
Example 2:
                                                                                                                                 score = 60
passing_score = 65
score < passing_score</pre>
                                                                                                                        returns True
                                                                                                                        Syntax:
                                                                                                                                for: # Code to repeat
   if # boolean statement
        break
for: # Code to repeat
   if # boolean statement
        continue
                                                                                                                        Example 1:
                                                                                                                                 for num in range(1, 6):
    if num == 3:
        break
                                                                                                                                        print(num)
                                   `break` exits the loop prematurely. `continue` skips the
Loop Controls
                                   rest of the current iteration and moves to the next
                                                                                                                        Example 2:
                                                                                                                                 for num in range(1, 6):
    if num == 3:
        continue
    print(num)
NOT
                                   Returns `True` if variable is `False`, and vice versa.
                                                                                                                        Syntax:
                                                                                                                                 not variable
                                                                                                                        Example:
                                                                                                                                 isLocked = False
print(not isLocked)
```

1	1	1
		returns True if the variable is False (i.e., unlocked).
		Syntax: variable1 != variable2
		Example: a = 10 b = 20 a != b
Not Equal(!=)	Checks if two values are not equal.	returns True Example 2: count=0 count != 0
		returns False
		<pre>Syntax: object_name = ClassName(arguments)</pre>
Object Creation	Creates an instance of a class (object) using the class constructor.	<pre>Example: person1 = Person("Alice", 25)</pre>
OR	Returns `True` if either statement1 or statement2 (or both) are `True`. Otherwise, returns `False`.	Syntax: statement1 or statement2
bout:blank		7

```
Example:
                                                                                                                          "Farewell Party Invitation"
grade = 12
if grade == 11 or grade == 12:
    print("Farewell Party Invitation")
else:
    print("Net eligible")
                                                                                                                                 print("Not eligible")
                                                                                                                  returns True
                                                                                                                  Syntax:
                                                                                                                           range(stop)
range(start, stop)
range(start, stop, step)
                                  Generates a sequence of numbers within a specified
range()
                                  range.
                                                                                                                  Example:
                                                                                                                           range(5) #generates a sequence of integers from 0 to 4. range(2, 10) #generates a sequence of integers from 2 to 9. range(1, 11, 2) #generates odd integers from 1 to 9.
                                                                                                                  Syntax:
                                                                                                                           return value
                                  `Return` is a keyword used to send a value back from a
Return Statement
                                                                                                                  Example:
                                  function to its caller.
                                                                                                                           def add(a, b): return a + b
result = add(3, 5)
Try-Except Block
                                  Tries to execute the code in the try block. If an
                                                                                                                  Syntax:
                                  exception of the specified type occurs, the code in the
                                                                                                                           try: # Code that might raise an exception except
ExceptionType: # Code to handle the exception
                                  except block is executed.
```

```
Example:
                                                                                                                   try:
    num = int(input("Enter a number: "))
except ValueError:
    print("Invalid input. Please enter a valid number.")
                                                                                                            Syntax:
                                                                                                                    try: # Code that might raise an exception except
ExceptionType: # Code to handle the exception
else: # Code to execute if no exception occurs
Try-Except with Else
                                Code in the 'else' block is executed if no exception
                                                                                                            Example:
Block
                                occurs in the try block.
                                                                                                                    try:
                                                                                                                          num = int(input("Enter a number: "))
                                                                                                                    except ValueError:
                                                                                                                          print("Invalid input. Please enter a valid number")
                                                                                                                    else:
                                                                                                                          print("You entered:", num)
                                                                                                            Syntax:
                                                                                                                    try: # Code that might raise an exception except
ExceptionType: # Code to handle the exception
finally: # Code that always executes
                                                                                                            Example:
Try-Except with
                                Code in the 'finally' block always executes, regardless
Finally Block
                                of whether an exception occurred.
                                                                                                                    try:
    file = open("data.txt", "r")
    data = file.read()
except FileNotFoundError:
    print("File not found.")
finally:
    file.close()
                                                                                                                          file.close()
While Loop
                                A `while` loop repeatedly executes a block of code as
                                                                                                            Syntax:
                                long as a specified condition remains `True`.
                                                                                                                    while condition: # Code to repeat
```

	<pre>Example: count = 0 while count < 5: print(count) count += 1</pre>
